

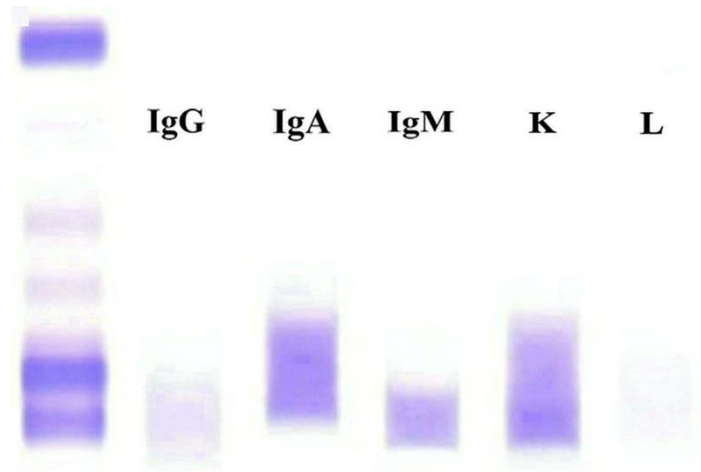

Fig. 1 Serum immunofixation study shows two paraproteins, IgM kappa and IgA kappa.

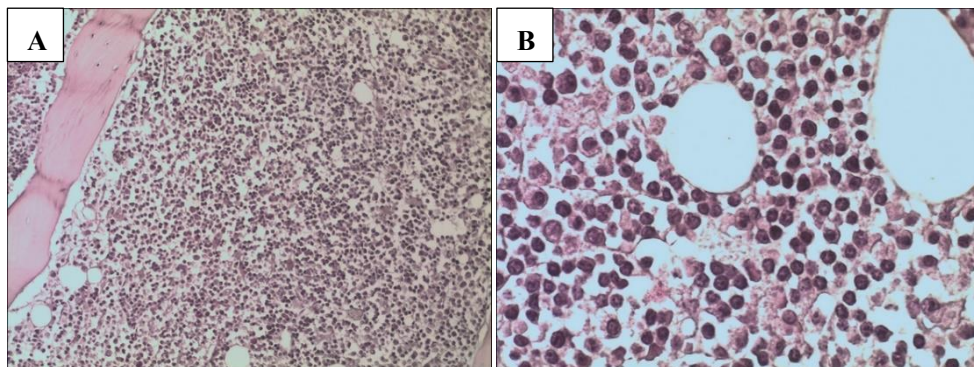

Fig. 2 (A) Bone marrow core biopsy shows an atypical lymphoid infiltrate in an interstitial and focally diffuse pattern. (B) Lymphocytes with partially plasmacytoma differentiation are small with occasional plasma cells.

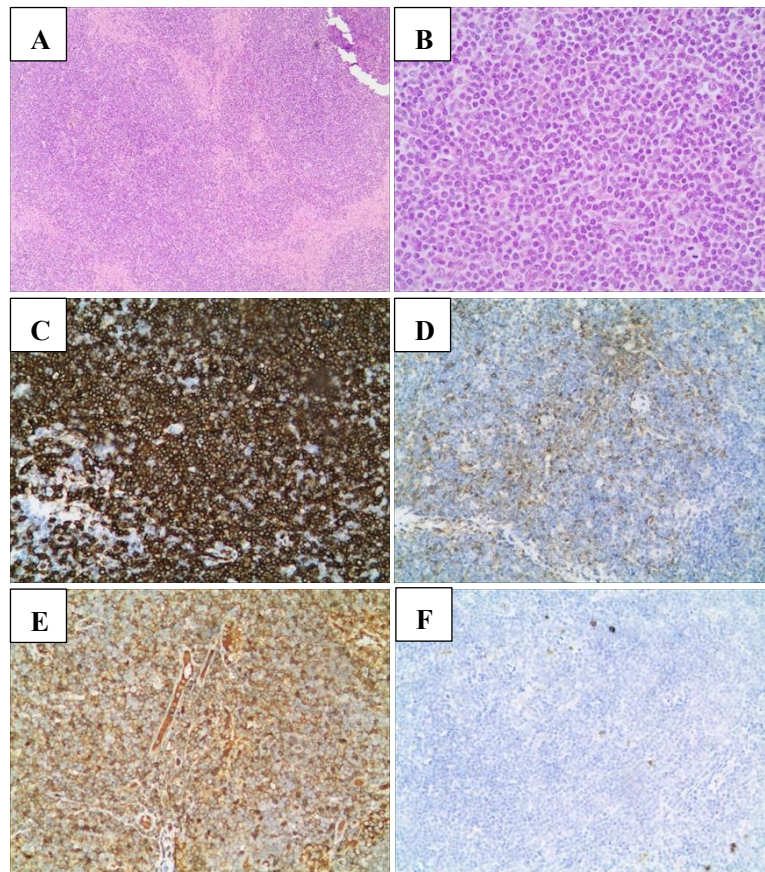

Fig. 3 (A) At low power, the lymph node architecture is effaced by diffuse lymphocytes proliferation. (B) At high power, the lymphoid infiltrate is composed of a mixture of small lymphocytes (predominant) and plasma cells (scattered). (C) Anti-CD20 highlights sheets of lymphocytes and (D) anti-CD138 highlights scattered and clustered plasma cells. Plasma cells are kappa light chain restricted by (E) kappa and (F) lambda immunostaining. In addition to plasma cells, kappa immunostaining also highlights plasmacytoid lymphocytes.
